## PS \#8

## 64. Solution:

Based on styrene, the reactivity sequence of monomers is:
Methacrylonitrile>Acrylonitrile>2-Vinyl pyridine>Styrene>Vinylidene chloride $>1,2$-bichloropropene-2 $>$ Vinyl chloride $>$ Allyl acetate

For methyl methacrylate:
2-Vinyl pyridine $>$ Methacrylonitrile $>$ Methyl methacrylate $>$ Acrylonitrile $>$ Vinylidene
chloride $>1,2$-bichloropropene-2 $>$ Vinyl chloride $>$ Allyl acetate
Table 5.3

For those monomers in this problem, generally we can arrange in the following way according to Table 5.3 (more reactive on the left).

## 65. Solution:

$\mathrm{M}_{1}$ is styrene, $\mathrm{M}_{2}$ is 1-Chloro-1,3-butadiene.

Assume we have $\mathbf{1 g}$ copolymer. Each $\mathrm{M}_{2}$ unit has one Cl atom, so the total mass of $\mathrm{M}_{2}$ in the copolymer is: $\mathrm{m}_{2}=1 *(\mathrm{Cl} w \mathrm{wt} \%)^{*}(88.54 / 35.45)$

The total mass of $M_{1}$ in the copolymer is $\left(1-\mathrm{m}_{2}\right)$;

| $\left.\mathrm{F}_{1}=\left(\mathrm{m}_{1} / 104.15\right) /\left\{\left(\mathrm{m}_{1} / 104.15\right)+\mathrm{m}_{2} / 88.54\right)\right\}$ |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | ---: | :---: |
| $\mathbf{f}_{\mathbf{1}}$ | $\mathbf{C ~ w t \% ~ i n ~}$ <br> polymer | Cl wt\% in <br> polymer | $\mathbf{m}_{\mathbf{2}}$ | $\mathbf{m}_{\mathbf{1}}$ | $\mathbf{F}_{\mathbf{1}}$ |  |
| 0.892 | 81.8 | 10.88 | 0.2717 | 0.7283 | 0.695 |  |
| 0.649 | 71.34 | 20.14 | 0.503 | 0.497 | 0.456 |  |

| 0.153 | 58.69 | 34.79 | 0.8689 | 0.1311 | 0.114 |  |

## 66. Solution:

$$
\begin{gathered}
\mathrm{F}_{1}=\frac{\mathrm{r}_{1} \mathrm{f}_{1}^{2}+\mathrm{f}_{1} \mathrm{f}_{2}}{\mathrm{r}_{1} \mathrm{f}_{1}^{2}+2 \mathrm{f}_{1} \mathrm{f}_{2}+\mathrm{r}_{2} \mathrm{f}_{2}^{2}} \\
\frac{\mathrm{f}_{1}\left(1-2 \mathrm{~F}_{1}\right)}{\mathrm{F}_{1}\left(1-\mathrm{f}_{1}\right)}=\mathrm{r}_{1}\left(\frac{\mathrm{f}_{1}^{2}\left(\mathrm{~F}_{1}-1\right)}{\mathrm{F}_{1}\left(1-\mathrm{f}_{1}\right)^{2}}\right)+\mathrm{r}_{2} \\
\mathrm{~A}=\mathrm{r}_{1} \mathrm{~B}+\mathrm{r}_{2}
\end{gathered}
$$

| $\mathbf{f 1}$ | F1 | A | B |
| :---: | :---: | :---: | :---: |
| 0.083 | 0.52 | -0.00696 | -0.00756 |
| 0.126 | 0.58 | -0.03977 | -0.01505 |
| 0.159 | 0.61 | -0.06819 | -0.02285 |
| 0.206 | 0.64 | -0.11351 | -0.03786 |

| 0.288 | 0.7 | -0.23114 | -0.07012 |
| 0.318 | 0.71 | -0.27583 | -0.0888 |
| 0.391 | 0.74 | -0.41646 | -0.14483 |
| 0.471 | 0.79 | -0.65368 | -0.21073 |
| 0.548 | 0.83 | -0.96407 | -0.30106 |

The data fit very well with the equation

## 67. Solution:

Eqn 5.7.4:

$$
\begin{gathered}
\mathrm{ki} / \text { ks }=\text { iso dyads/syndio dyads }=\mathrm{Ai} / \mathrm{Ae}^{*} \exp \left\{-\left(\mathrm{Ei}^{*}-\mathrm{Es}^{*}\right) / \mathrm{RT}\right\} \\
\ln \left(\mathrm{k}_{\mathrm{i}} / \mathrm{k}_{\mathrm{s}}\right)=-\left(\mathrm{Ei}^{*}-\mathrm{Es}^{*}\right) / \mathrm{RT}+\mathrm{C}
\end{gathered}
$$

* $\beta$ is the probability of an isotactic placement in the products, so (1- $\beta$ ) is the probability of a syndiotactic placement.

$$
\mathrm{ki} / \mathrm{ks}=\text { iso dyads/syndio dyads= } \beta /(1-\beta)
$$

## 68. Solution:

$$
\begin{gather*}
N_{n i}=N_{n s}  \tag{5.9.1}\\
p_{h}=\frac{v_{h}}{v_{h}+v_{i}+v_{s}}=\frac{\sum N_{n i}=\sum N_{n s}}{\sum N_{n i}+\sum N_{n s}+\sum N_{n i}\left(n_{i}-1\right)+\sum N_{n s}\left(n_{s}-1\right)} \\
=\frac{\left(\sum N_{n i}+\sum N_{n s}\right)}{\left\{\sum N_{n i}+\sum N_{n s}+\sum N_{n i}\left(n_{i}-1\right)+\sum N_{n s}\left(n_{s}-1\right)\right\}} * \frac{1 / \sum N_{n s}}{1 / \sum N_{n s}} \\
p_{h}=\frac{2}{\overline{n_{i}}+\overline{n_{s}}}
\end{gather*}
$$

From the expression, $\overline{n_{s}}$ should be equally important as $\overline{n_{i}}$. The proposition is wrong. The sequence DL is an " r ", it has a $50: 50$ chance to be rm (hetero) or rr (syndio). The DD is an
" m ", half way to hetero mr or iso mm
69.

## Solution:

| Catalyst | Fraction of polymer |  |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  |  | $\mathrm{T},{ }^{\circ} \mathrm{C}$ | Iso | Hetero |
|  |  | Methyl methacrylate | Syndio |  |  |
| Thermal |  | 60 | 8 | 33 | 59 |
| n-Butyl lithium |  | -78 | 78 | 16 | 6 |
| n-Butyl lithium | Methyl isobutyrate | -78 | 21 | 31 | 48 |
|  |  | $\alpha-$ Methyl styrene |  |  |  |
| $\mathrm{TiCl}_{4}$ | Toluene | -78 | - | 19 | 81 |
| $\mathrm{Et}_{3} \mathrm{Al} / \mathrm{TiCl}_{4}$ | Benzene | 25 | 3 | 35 | 62 |
| $\mathrm{n}-\mathrm{Butyl}$ lithium | Cyclohexane | 4 | - | 31 | 69 |

*Calculate $\mathrm{P}_{\mathrm{m}} \mathrm{s}$ separately based on three components in each reaction, and then use the averaged Pm for each reaction condition to plot point in the following figures.

## For methyl methacrylate:

## For $\alpha$-methyl styrene:

From above figures, zero-order Markov statistics apply to all free radical, cationic polymerizations, and also apply to Ziegler-Natta catalyzed systems. However, for anionic reactions, there are bigger deviations, so higher-order Markov statistics may be needed.

## 70. Solution:

Under chain-end control, the addition of a monomer is influenced most by the configuration of the previous repeat unit. Under site control the ligand set may be chosen to provide a chiral confining environment, which determines the stereochemistry of addition.

Basically, if you have site control, a stereodefect is immediately "corrected". i.e. DDDDDLDDDDD. In other words, the catalyst knows D from L . This gives mmmmrmmmm, i.e. r's always occur in pairs. For chain end control, isospecific means "keep adding the same way". It does not prefer D to L. A defect looks like this: DDDDDDLLLLLLL, or mmmmmmrmmmm, i.e. r's occur singly. This can be seen in the triads.
